Description

BTSs on the A-bis OML protocol have a means how ALERTS/ALARMS in the BTS can be communicated back to the BSC.

However, the BSC should also report abnormal conditions inside the BSC as some kind of ALERT/ALARM.

This could possibly be more or less automatic, maybe we should simply offer a way how "ERROR" level log messages can be designated an ALARM and exported via the control interface? However, ALARMS typically get raised and can cease later again - that wouldn't work for log messages.
